

# 01 Project Documentation Incident Lifecycle Automation

## Incident Lifecycle Automation in ServiceNow

### Project Overview

This project implements a structured Incident Management lifecycle in ServiceNow, covering incident creation, classification, knowledge-assisted investigation, escalation, Level 2 support, emergency change linkage, child incidents, resolution and closure, knowledge creation, and final validation.

### Purpose

The documentation provides a consistent reference for the planned solution, its functional flow, roles, related records, validation activities, and deployment-readiness considerations.

### Scope

- Incident Management lifecycle from creation through closure.
- Service and Service Offering setup and association.
- Incident classification using Category, Subcategory, Urgency, Service, and Configuration Item.
- Knowledge Management and Agent Assist support.
- Assignment and escalation to Level 2 support.
- Emergency Change Request and Child Incident relationships.
- Resolution, closure information, and knowledge article creation.
- Final validation of incident, SLA, change, child incident, knowledge, and related records.
- Testing and deployment validation.

### Users and Roles

- Service Desk Agent — creates, classifies, assigns, investigates, and updates incidents.
- Level 2 Technician — investigates escalated incidents and records technical findings.
- Service Owner / Support Stakeholders — provide service context and support oversight.
- Change Stakeholders — review and manage emergency changes when required.
- Project Team — validates the lifecycle and deployment readiness.

### Expected Benefits

- Standardized Incident Management process.
- Faster handling and improved routing.
- Better incident classification and information quality.
- Improved escalation and Level 2 context.
- Traceability between incidents, changes, and child incidents.

- Complete resolution documentation and reusable knowledge.
- Improved SLA and related-record visibility.

### **Documentation Status**

This document describes the designed/planned solution. Actual execution evidence, production results, and screenshots should be added after implementation and validation.

# 02 Functional Design Document Incident Lifecycle Automation

## Incident Lifecycle Automation in ServiceNow

### Functional Flow

Create Service/Service Offering → Create Incident → Classify Incident → Use Knowledge/Agent Assist → Assign/Escalate → Level 2 Investigation → Link Emergency Change or Child Incident when required → Resolve and Close → Create Knowledge Article → Validate Related Records and SLA → Test and Validate Deployment.

### Incident Classification

- Category
- Subcategory
- Urgency
- Service
- Configuration Item (CI)

### Lifecycle Requirements

- The incident should contain sufficient information for triage and routing.
- Classification should be completed consistently.
- Knowledge and Agent Assist should support troubleshooting.
- Escalated incidents should retain context for Level 2.
- Emergency changes should be traceable to the incident when required.
- Recurring or related issues should be represented using child incidents.
- Cause, Resolution, Resolution Details, and closure information should be documented.
- Useful troubleshooting information should be eligible for conversion into a Knowledge Article.

### Validation Checklist

- Incident record is created and classified.
- Service and Service Offering are correct.
- SLA/related records are visible and traceable.
- Emergency Change is linked where applicable.
- Child Incident is linked where applicable.
- Knowledge/Agent Assist information is available as designed.
- Resolution and closure information is complete.
- Knowledge Article is created when applicable.
- End-to-end workflow passes testing and deployment validation.

## 03 User Guide Incident Lifecycle Automation

### Incident Lifecycle Automation in ServiceNow

#### Service Desk Agent

- Open the Incident Management interface.
- Create a new incident and enter the required incident information.
- Select Category, Subcategory, Urgency, Service, and CI.
- Use available Knowledge or Agent Assist information during troubleshooting.
- Assign or escalate the incident when additional support is required.
- Link an Emergency Change or create/link a Child Incident when appropriate.
- Record Cause, Resolution, Resolution Details, and closure information.
- Validate the incident and related records before closure.

#### Level 2 Technician

- Review the escalated incident and its existing context.
- Investigate the technical issue.
- Review related knowledge and associated records.
- Update findings and resolution information.
- Coordinate related change or child-incident activity when required.
- Return the incident for resolution/closure after investigation.

#### Change Stakeholders

- Review emergency change requests linked to incidents.
- Validate change context and relationship to the incident.
- Support change completion and traceability.

#### Important Note

The exact navigation labels, field values, and UI behavior depend on the final ServiceNow configuration. This guide should be updated with screenshots after the implementation is executed.

# 04 Testing and Deployment Validation Incident Lifecycle Automation

## Incident Lifecycle Automation in ServiceNow

### Functional Validation

- Validate Service and Service Offering configuration.
- Validate Incident creation and mandatory information.
- Validate Category, Subcategory, Urgency, Service, and CI classification.
- Validate Knowledge Management / Agent Assist usage.
- Validate assignment and Level 2 escalation.
- Validate Emergency Change relationship.
- Validate Child Incident relationship.
- Validate resolution and closure fields.
- Validate Knowledge Article creation.
- Validate SLA and related-record visibility.

### End-to-End Test Scenario

Create an incident → classify it → investigate using knowledge support → escalate to Level 2 → create/link related change or child incident where applicable → document cause and resolution → close the incident → create reusable knowledge → verify all related records and SLA information.

### Deployment Readiness

- All planned functional tests completed.
- No unresolved critical defects.
- Incident, change, child-incident, knowledge, SLA, and related-record relationships verified.
- User acceptance evidence captured.
- Deployment validation completed.

### Status

Execution results are not asserted in this document because the uploaded project documentation materials do not provide actual execution evidence.
